Internship and Job Application Assistant

Applying for internships and entry-level jobs is very time consuming. Applicants are usually required to submit personalized cover letters and resumes for each job position. They are also required to analyze job postings that suit their relevant skills, and track application deadlines and follow-ups. This can be very stressful, especially for students and new graduates entering the workforce. For many college students, an internship is not just optional, but a graduation requirement. For example Georgia State requires students in certain fields to complete an internship credit or an alternative capstone credit.

The internship and job application process is very repetitive and time consuming. Most of the existing automated tools available for application assistance usually handle only single steps in the application process, not addressing how these steps are all interconnected. An AI agentic system is a good solution for this problem because it can handle multiple related tasks, use feedback to improve its outputs, and provide personalized assistance throughout each step of the application process.

The target users for this AI agentic system are students searching for internships or entry-level jobs, and recent graduates and individuals entering the workforce. These users often have to apply to a large amount of positions in a short amount of time. This can make it difficult to create personalized cover letters or resumes for each position.

User Scenarios

User Scenario #1: *A user wants a customized cover letter and resume for a specific role.* Tasks agent will perform- Analyze company job description, generate a customized cover letter or resume.

User Scenario #2: *A user wants to apply to multiple jobs and stay organized.* Tasks agent will perform: Record upcoming application deadlines, Notify user of follow up responses.

Initial System Deadline

This AI agentic system will work with many different agents to support the application system. A job analysis agent will look for job postings that match the users skills. A resume enhancement agent will be responsible for tailoring resume content to fit certain job descriptions. A cover letter agent will be responsible for generating customized cover letters based on job description and resume. An application tracking agent will keep a record of submitted applications and will inform users of any follow up responses. The system will use a large language model API to understand the meaning of papers and produce text. Resume and job description can be provided by users as either text or PDF format. Data from the application will be kept in a simple local database, such as SQLite or JSON. The system will be easy to use, where users can upload documents, view results, and monitor the status of their application.

Feasibility & Risks

Potential challenges include the risk of hallucinated generated content, making resumes too customized so they do not work for other job positions, and limitations of the tools such as usage limits or slow responses. There is also a privacy concern because users will be uploading very personal information into the AI system. All these risks will be addressed by carefully moderating how prompts are given, and only storing the necessary data into the system.
