

Milestone II – Multi-Agent Workflow Design Document

Project: AI Terms and Policy Translator

The goal of this project is to build an AI system that helps users understand long terms and conditions, privacy policies, and online agreements before accepting them. Many people, especially college students applying for internships or jobs, often click agree without reading the policy because the language is difficult to understand and the documents are very long. This system is designed to make those policies easier to read by using multiple AI agents that work together. The user can paste a policy into the interface, and the system analyzes the text, explains it in simple language, and points out possible risks. Instead of using only one AI response, the system uses a multi agent workflow where each agent has a different job. This makes the results more organized and easier to control.

The system follows a fixed workflow where the output of one agent becomes the input for the next agent. The user interacts with a simple front end interface built in Opal. After the user enters the policy text, the workflow sends the text through several agents in a specific order. Each agent focuses on one task so the final result is clearer. The workflow includes a policy parser agent, a simplification agent, a risk detection agent, and a formatter agent. These agents run in sequence and pass information to each other until the final result is produced. This structure satisfies the requirement for a multi agent system because the task is divided into different roles and the agents communicate through a controlled pipeline.

The first agent in the system is the policy parser agent. The purpose of this agent is to read the original policy and figure out the important parts of the document. Policies usually contain different topics in the same text, such as privacy rules, payment terms, account limits, and legal statements. The parser agent separates the policy into clear sections so the rest of the system can understand what the document is talking about. The input for this agent is the raw text that the user enters, and the output is a more organized version of the policy that highlights the main ideas. This step makes the rest of the workflow easier because the following agents do not need to read the entire document at once.

The second agent is the simplification agent. The job of this agent is to rewrite the policy in plain English so that a normal user can understand it. Many policies use legal words that students or non technical users may not know. The simplification agent keeps the meaning the same but explains it in a clearer way. The input for this agent is the organized text from the parser agent, and the output is a simpler explanation of the policy. This step is important because the goal of the project is not only to analyze the policy but also to make sure the user actually understands what they are agreeing to.

The third agent is the risk detection agent. This agent looks for parts of the policy that could cause problems for students who are applying for internships, jobs, or online platforms. Some policies include rules about sharing personal data, charging subscription fees, checking background information, or deleting accounts without warning. These are the kinds of things users often miss when they read quickly. The risk agent scans the simplified text and finds clauses that might be important or dangerous. It then explains why each one could be a problem and gives a level of concern such as low, medium, or high. The input for this agent is the simplified policy, and the output is a list of risks with explanations. This helps the user understand what could happen before agreeing to the policy.

The last agent in the workflow is the formatter agent. The role of this agent is to take the results from the previous agents and turn them into a clean final response. Instead of showing raw analysis, the formatter organizes the information into a summary, key points, risks, and a final recommendation. The summary explains what the policy is about, the key points describe the most important rules, the risks section shows possible problems, and the recommendation tells the user if the policy seems safe or if they should be careful. The input for this agent is the text created by the risk detection agent, and the output is the final result that the user sees on the screen. This step makes the system easier to use for someone who does not want to read technical details.

The agents communicate using a fixed pipeline where each step sends its result to the next step. The workflow controller makes sure the agents run in the correct order and that the information flows from the user input to the final output. This type of coordination is simple but works well for this project because each agent only needs to do one job. If something goes wrong, it is easier to see which step caused the problem and fix it.

There are some limits to the system that could affect the results. Some policies may be very long or written in unusual legal language, which can make it harder for the parser or simplification agent to understand everything correctly. The risk detection agent may also mark something as risky even if it is normal for that type of service. Because of this, the system is designed to give helpful explanations but not legal advice. The formatter agent helps reduce confusion by showing the results in a clear and consistent way. In the future, the system could be improved by using better tools for reading long documents or adding more advanced checks for legal language.

Overall, the multi agent design makes the system more realistic and easier to use. Each agent has a clear role, the workflow is organized, and the final result is easy to understand for students and everyday users. This design meets the requirements for the project because it uses multiple agents with different responsibilities, a defined workflow, a working interface, and a clear explanation of how the system works.
